

# Recurrent Neural Networks (RNN)

# Language Modeling

- **Language Modeling** is the task of predicting what word comes next.

- More formally: given a sequence of words  $x^{(1)}, x^{(2)}, \dots, x^{(t)}$ , compute the probability distribution of the next word  $x^{(t+1)}$  :

$$P(x^{(t+1)} \mid x^{(t)}, \dots, x^{(1)})$$

where  $x^{(t+1)}$  can be any word in the vocabulary  $V = \{w_1, \dots, w_{|V|}\}$

- A system that does this is called a **Language Model**.

# n-gram Language Models

- First we make a **simplifying assumption**:  $\mathbf{x}^{(t+1)}$  depends only on the preceding  $n-1$  words.

$$P(\mathbf{x}^{(t+1)} | \mathbf{x}^{(t)}, \dots, \mathbf{x}^{(1)}) = P(\mathbf{x}^{(t+1)} | \overbrace{\mathbf{x}^{(t)}, \dots, \mathbf{x}^{(t-n+2)}}^{n-1 \text{ words}}) \quad (\text{assumption})$$

prob of a n-gram  $\rightarrow$

prob of a (n-1)-gram  $\rightarrow$

$$= \frac{P(\mathbf{x}^{(t+1)}, \mathbf{x}^{(t)}, \dots, \mathbf{x}^{(t-n+2)})}{P(\mathbf{x}^{(t)}, \dots, \mathbf{x}^{(t-n+2)})} \quad \left| \quad \begin{array}{l} \text{(definition of} \\ \text{conditional prob)} \end{array} \right.$$

- Question:** How do we get these  $n$ -gram and  $(n-1)$ -gram probabilities?
- Answer:** By **counting** them in some large corpus of text!

$$\approx \frac{\text{count}(\mathbf{x}^{(t+1)}, \mathbf{x}^{(t)}, \dots, \mathbf{x}^{(t-n+2)})}{\text{count}(\mathbf{x}^{(t)}, \dots, \mathbf{x}^{(t-n+2)})} \quad \begin{array}{l} \text{(statistical} \\ \text{approximation)} \end{array}$$

# A fixed-window neural language model

output distribution

$$\hat{\mathbf{y}} = \text{softmax}(\mathbf{U}\mathbf{h} + \mathbf{b}_2) \in \mathbb{R}^{|V|}$$

hidden layer

$$\mathbf{h} = f(\mathbf{W}\mathbf{e} + \mathbf{b}_1)$$

concatenated word embeddings

$$\mathbf{e} = [\mathbf{e}^{(1)}; \mathbf{e}^{(2)}; \mathbf{e}^{(3)}; \mathbf{e}^{(4)}]$$

words / one-hot vectors

$$\mathbf{x}^{(1)}, \mathbf{x}^{(2)}, \mathbf{x}^{(3)}, \mathbf{x}^{(4)}$$

~~as the prof started the clock~~  
discard

the students opened their  
context

# A fixed-window neural Language Model

**Improvements** over  $n$ -gram LM:

- No sparsity problem
- Don't need to store all observed  $n$ -grams

Remaining **problems**:

- Fixed window is **too small**
- Enlarging window enlarges  $W$
- Window can never be large enough!
- $x^{(1)}$  and  $x^{(2)}$  are multiplied by completely different weights in  $W$ .  
**No symmetry** in how the inputs are processed.

We need a neural architecture that can process *any length input*

# Recurrent Neural Networks (RNN)

A family of neural architectures

Core idea: Apply the same weights  $W$  repeatedly

# A RNN Language Model

output distribution

$$\hat{y}^{(t)} = \text{softmax}(U h^{(t)} + b_2) \in \mathbb{R}^{|V|}$$

hidden states

$$h^{(t)} = \sigma(W_h h^{(t-1)} + W_e e^{(t)} + b_1)$$

$h^{(0)}$  is the initial hidden state

word embeddings

$$e^{(t)} = E x^{(t)}$$

words / one-hot vectors

$$x^{(t)} \in \mathbb{R}^{|V|}$$

$$\hat{y}^{(4)} = P(x^{(5)} | \text{the students opened th})$$

## RNN **Advantages:**

- Can process **any length** input
- Computation for step  $t$  can (in theory) use information from **many steps back**
- **Model size doesn't increase** for longer input
- Same weights applied on every timestep, so there is **symmetry** in how inputs are processed.

## RNN **Disadvantages:**

- Recurrent computation is **slow**
- In practice, difficult to access information from **many steps back**

More on these later in the course

# Training the RNN model

- Get a **big corpus of text** which is a sequence of words  $x^{(1)}, \dots, x^{(T)}$
- Feed into RNN-LM; compute output distribution  $\hat{\mathbf{y}}^{(t)}$  **for every step  $t$** .
  - i.e. predict probability dist of *every word*, given words so far
- **Loss function** on step  $t$  is **cross-entropy** between predicted probability distribution  $\hat{\mathbf{y}}^{(t)}$ , and the true next word  $\mathbf{y}^{(t)}$  (one-hot for  $x^{(t+1)}$ ):

$$J^{(t)}(\theta) = CE(\mathbf{y}^{(t)}, \hat{\mathbf{y}}^{(t)}) = - \sum_{w \in V} \mathbf{y}_w^{(t)} \log \hat{\mathbf{y}}_w^{(t)} = - \log \hat{\mathbf{y}}_{x_{t+1}}^{(t)}$$

- Average this to get **overall loss** for entire training set:

$$J(\theta) = \frac{1}{T} \sum_{t=1}^T J^{(t)}(\theta) = \frac{1}{T} \sum_{t=1}^T - \log \hat{\mathbf{y}}_{x_{t+1}}^{(t)}$$

# Training the RNN model

# Training the RNN model

# Backpropagation

## Backpropagation for RNNs

**Question:** What's the derivative of  $J^{(t)}(\theta)$  w.r.t. the **repeated** weight matrix  $W_h$  ?

**Answer:** 
$$\frac{\partial J^{(t)}}{\partial W_h} = \sum_{i=1}^t \frac{\partial J^{(t)}}{\partial W_h} \Big|_{(i)}$$

"The gradient w.r.t. a repeated weight is the sum of the gradient w.r.t. each time it appears"

Why?

# MCR

## Multivariable Chain Rule

- Given a multivariable function  $f(x, y)$ , and two single variable functions  $x(t)$  and  $y(t)$ , here's what the multivariable chain rule says:

$$\underbrace{\frac{d}{dt} f(x(t), y(t))}_{\text{Derivative of composition function}} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt}$$

Derivative of composition function

# Lets have a real example

# Generating text with a RNN Language Model

Just like a n-gram Language Model, you can use a RNN Language Model to **generate text** by **repeated sampling**. Sampled output is next step's input.

# RNNs can be used for tagging

e.g. part-of-speech tagging, named entity recognition

# RNNs can be used for sentence classification

e.g. sentiment classification
